This difficulty arises from many different sources, including software bugs, hardware defects, memory problems, over-heating, supply voltage fluctuations, etc. In the course of normal operation, these problems may not cause device failure, but can cause a device to fail prematurely. For example, a sudden drop in supply voltage may cause a device to restart, shutting the device off from its work, and reducing the device's availability for use. These problems often manifest themselves as slowly-degrading errors—errors that may eventually cause a device to stop operating. One device that is commonly used to identify problems is the computer's processor. The operation of the processor can be monitored by software or hardware in the computer. In some cases, monitoring processor activity can be performed during operation of the computer, and can assist the computer user in identifying potential problems. For example, a user may access various processor monitoring functions in order to determine if a potential problem is occurring. For example, if the processor is generating a low supply voltage, the user can be informed that there is a problem, allowing the user to take appropriate action. Although other aspects of computer, tablet, smart phone, etc. operation may be monitored, the nature of modern computing systems dictates that many such devices may be more complex than the monitoring provided by processor monitoring alone. For example, modern electronic devices may include multiple processors, memory components, hard disk drives, network interfaces, video output components, camera interfaces, etc., which may interact in various ways with the processor. Such interactions make it difficult to collect and analyze data about processor activity in the context of other components in the computing system. In addition, due to the nature of the computing system, multiple devices may be failing or experiencing errors at any time, and it may be difficult to ascertain which of these errors is having the greatest impact on the computing system. This problem may be compounded by the fact that relatively few systems may be able to collect or identify data regarding device operating parameters, which can be used to identify 3da54e8ca3
